(54) Arrangement for resource and work-item selection

(57) A workflow system (FIG. 1) employs a selection engine (114) that attempts to match work items (100) with resources (104) in such a way that it brings the most value to all of the stakeholders in the workflow. Under resource surplus conditions (FIG. 4), the selection engine determines those available resources that possess skills needed by an available work item, for each determined resource determines both a business value (RSBV) of having that resource service the work item and a value (RTV) to that resource of servicing the work item, and then selects the resource that has a best combined value of the business value and the value to the resource to serve the work item. Under work-item surplus conditions (FIG. 5), the selection engine determines those available work items that need skills possessed by an available resource, for each determined

work item determines both a business value (WSBV) of having that work item serviced by the resource and a value (WTW) to that work item of being serviced by the resource, and then selects the work item that has a best combined value of the business value and the value to the work item to be served by the resource. The business value is a scaled (normalized) sum of products of a proficiency level of the resource in each of the skills and the weight (BR) of that skill of the work item. The value to a resource or work item is a scaled sum of products of scaled resource treatments (T) or work item treatments (C) (actual and/or goal) and weights (TW,CW) given to those respective treatments by the work item.

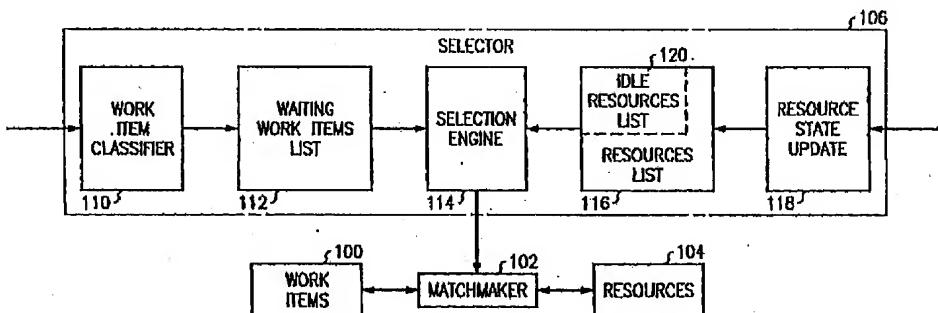

FIG. 1

Description**Technical Field**

5 [0001] This invention relates to workflow management.

Background of the Invention

10 [0002] In a workflow, work items-be they physical items like products and paper documents or virtual items like communications and electronic documents-progress through one or more steps of processing each performed by resources, e.g., workmen, machines, agents, that are allocated in whole or in part to those stages. Representative workflows include call centers and assembly lines.

15 [0003] Traditional call-center resource and work-item selection algorithms have been limited by the call-center model presented by the automatic call distribution (ACD) switch. These conventional workflows generally employ a first-in, first-out (FIFO) selection algorithm at each state: the first available resource handles the first available work item. While variations on this basic algorithm have been developed over time, the underlying algorithm remains the same. For example, one known ACD switch represents resources as having skills and skill levels, and provides multi-priority queues for queuing work items to wait for resources with corresponding skills to become available. So any algorithms that are applied to this model are constrained by its limited and fixed structure. This conventional approach handles simple deviations from the underlying FIFO selection principle. But it quickly becomes unwieldy when used to implement a complex or flexible selection algorithm such as may be needed to select a "best" work item for the "best" resource. The limitations of this conventional approach become evident when one considers the example of an insurance company that sells three types of insurance, each one of whose agents must be licensed to sell each of these types of insurance on a state-by-state basis, and whose call center allows callers to select English-speaking or Spanish-speaking agents. 20 This results in 300 possible combinations of skill requirements. Administering the conventional ACD switch for all of these combinations would be difficult if not impossible.

Summary of the Invention

30 [0004] This invention is directed to solving these and other problems and disadvantages of the prior art. Generally according to the invention, there is provided a new workflow resource-selection and work-item-selection arrangement that attempts to match work items with resources in such a way that it brings the most value to all of the stakeholders in the workflow. This may include customers, resources, managers, etc. The arrangement defines resources as having particular skills and preferably also levels of proficiency in those skills, as is conventional. It classifies work items when they arrive for processing as requiring certain skills, as is also conventional. Under resource surplus conditions, the arrangement determines those available resources that possess skills needed by an available work item, for each determined resource determines both a business value of having that resource service the work item and a value to that resource of servicing the work item, and then selects the resource that has a best combined value of the business value and the value to the resource to serve the work item. Under work-item surplus conditions, the arrangement determines those available work items that need skills possessed by an available resource, for each determined work item determines both a business value of having that work item serviced by the resource and a value to that work item of being serviced by the resource, and then selects the work item that has a best combined value of the business value and the value to the work item to be served by the resource. The arrangement may thus be viewed as setting goals for work-item processing and resource treatment and then matching work items to resources in a way that optimizes the workflow to bring the most value to all of the stakeholders in the workflow. Illustratively, the arrangement indicates a weight for each skill needed by a work item, and the business value is computed as a sum of products of a proficiency level of the resource in each of the skills and the weight of that skill of the work item. Further illustratively, the arrangement keeps track of treatments that are being given to resources and work items, e.g., for resources, a time since the resource became available, a time that the resource has not spent serving work items, and a measure of an effect that 35 serving a work item would have on a goal of the resource; and for work items, a time that the work item has been waiting for service, an estimated time that the work item will have to wait for service, and a time by which the work item has exceeded its target wait time. The values to the resource and to the work item are then computed from these treatments. Illustratively, the arrangement indicates a weight to be given to each of the treatments, whereupon the value to a resource is computed as a sum of products of each treatment of the resource and the weight of the treatment, and the value to a work item is computed as a sum of products of each treatment of the work item and the weight of that treatment.

40 [0005] Preferably, all of the computed values are scaled, i.e., normalized, to ensure that the degree of their effect on the final combined value stays within predetermined bounds. Therefore, determining a business value preferably

Involves determining a weighted business value, which is the business value weighted by a business value weight that is preferably common to all available or determined resources under resource surplus conditions and to all or available or determined work items under work-item surplus conditions. Also, determining a value to the resource preferably involves determining a weighted value to the resource, which is the value to the resource weighted by a resource value weight that is preferably common to all available or determined resources, and determining a value to the work item preferably involves determining a weighted value to the work item, which is the value to the work item weighted by a work item value weight that is preferably common to all available or determined work items. Selecting a resource or a work item then involves selecting the resource or work item that has the best combined value (e.g., sum) of the weighted business value and the weighted value to the resource or work item.

10 [0006] Depending on implementation, the invention offers one or more of the following advantages.

- Allows for substantially an unlimited number of skills (limited by computing power only)
- Provides for an individual weighting of multiple skills that are required to process each work item
- Considers both required and non-required skills
- Considers and weights multiple skill levels across multiple skills
- Each work item can receive a different priority weight for business value, resource fairness, and work-item fairness
- Each work item can receive a different priority weight for different categories of resource fairness
- Each work item can receive a different priority weight for different categories of work-item fairness
- Allows for extensive customization of the process of matching resources with work items—even on a work-item-specific or a resource-specific basis.
- An estimated "time to service" is calculated for work items requiring multiple skills for service based on the weighting of those skill requirements, the number of work items waiting for service and their skill requirement weighting, and "time to service" of work items already distributed to resources.
- The "time to service" calculation is based on a single vector, allowing for easy distribution of workflow across multiple sites and centralization of the site selection decision.

[0007] While the invention has been characterized in terms of a method, it also encompasses apparatus that performs the method. The apparatus preferably includes an effector—any entity that effects the corresponding step, unlike a means—for each method step. The invention further encompasses a computer-readable medium containing instructions which, when executed in a computer, cause the computer to perform the method steps.

[0008] These and other features and advantages of the invention will become more apparent from a description of an illustrative embodiment of the invention considered together with the drawing.

Brief Description of the Drawing

35 [0009]

FIG. 1 is a block diagram of a work-processing system that includes an illustrative embodiment of the invention; FIG. 2 is a block diagram of a work-item classification of the system of FIG. 1; FIG. 3 is a block diagram of a resource qualification of the system of FIG. 1; FIG. 4 is a functional flow diagram of operations of a selection engine of the system of FIG. 1 in times of resource surplus; and FIG. 5 is a functional flow diagram of operations of the selection engine of the system of FIG. 1 in times of work-item surplus.

Detailed Description

1. The Environment

50 [0010] FIG. 1 shows an illustrative work processing system that comprises work items 100 waiting to be processed, resources 104 that process work items 100, a match-maker 102 that assigns individual work items 100 to individual resources 104 for processing, and a selection arrangement (SELECTOR) 106 that controls match-maker 102 and determines which work item 100 should be assigned to which resource 104. By way of one example, the processing system may be a call center wherein work items 100 comprise waiting communications, resources 104 comprise agents and interactive response systems, match-maker 102 comprises an automatic communications distributor (ACD), and selection arrangement 106 comprises either an adjunct processor to the ACD or a control program residing in memory of the ACD and executing on a processor of the ACD. As described so far, the work processing system of FIG. 1 is conventional.

2. Selection Arrangement Algorithm

[0011] The goal of selection arrangement 106 is to match work items 100 and resources 104 in a way that it brings the most value to all of the stakeholders in the work processing system. This includes customers, resources, managers, etc. According to the invention, to perform this optimization, selection arrangement 106 evaluates three components of a work item 100-to-resource 104 match.

2.1 The Three System Values

10 2.1.1 Business Value BV

[0012] The business value (BV) of a work item 100-to-resource 104 match is a measure of resource 104 qualification for work-item 100 handling based on resource 104 skills and skill proficiencies and work-item 100 skill requirements.

15 2.1.2 Resource Treatment Value RTV

[0013] The resource treatment value (RTV) of a work item 100-to-resource 104 match is a measure of how a resource 104 is spending time compared with other resources 104, as well as individual resource 104 goals.

20 2.1.3 Work Item Treatment Value WTV

[0014] The work item treatment value (WTV) of a work item 100-to-resource 104 match is a measure of how a work item 100 is treated compared to other work items 100, as well as individual treatment goals for the specific work item 100.

2.2 The Two Basic System States

[0015] Evaluation of the three system values discussed above depends on the state of the work processing system at the time of evaluation. The two possible states for a system and their effect on the application of the three system values is described next.

2.2.1 Resource Surplus RS

[0016] If there are idle resources 104 waiting for a work item because there are no waiting work items 100 for which the idle resources 104 have the "required" skills or there are no waiting work items 100 at all, the system is considered to be in a state of resource surplus (RS). In the case of resource surplus, when a work item 100 arrives in the system, the objective is to find the best resource 104 to handle the work item 100. So, one would evaluate the business value and the resource treatment value of each resource 104 matched with the new work item 100, looking for the resource 104-to-work item 100 match that brought the highest value to the organization. For this case of resource surplus, work item treatment is not an issue because the work item 100 will receive immediate handling, provided that there is a resource 104 available with the required skills.

2.2.2 Work Item Surplus WS

[0017] If there are no idle resources 104 in the system or there are no idle resources 104 that have the required skills to service any waiting work items 100 and there are work items 100 waiting for resource 104 assignment, the system is considered to be in a state of work item surplus (WS). In the case of work item surplus, when a resource 104 becomes available to handle work items 100, the objective is to find the best work item 100 for the resource 104 to handle. So, one would evaluate the business value and the work item treatment value of each work 100 item matched with the newly-available resource 104, looking for the resource 104-to-work item 100 match that brings the highest value to the organization. For the case of work item surplus, resource treatment is not an issue, because the resource 104 will receive the work item 100 immediately upon becoming available, provided that there is a work item 100 available for which the resource 104 has the required skills.

2.3 Calculation of Business Value

[0018] Assume that a matrix $A_{\text{availresources}, \text{maxskills}}$, where availresources is the number of available resources 104 and

maxskills is the maximum number of skills defined in the system, represents the available resources 104 and their associated skill levels such that $A_{n,m}$ represents the skill level (an integer between 0 and 10, for example) for resource n and skill m .

[0019] Also, assume that a matrix $BR_{\text{pendingworkitems}, \text{maxskills}}$, where pendingworkitems is the number of unserviced work items 100 in the system and maxskills is the maximum number of skills defined in the system, represents the skill weight of the work item 100 such that $BR_{n,m}$ represents the skill weight (an integer between 0 and 10) for work item n and skill m .

[0020] Lastly, assume that a matrix $BRR_{\text{pendingworkitems}, \text{maxskills}}$, where pendingworkitems is the number of unserviced work items 100 in the system and maxskills is the maximum number of skills defined in the system; represents the requirement of a skill for a work item 100 such that $BRR_{n,m}$ (true or false) indicates whether a resource 104 must have a skill level > 0 in skill m to handle work item n . This array is not used in the calculation of business value, but is used farther below.

2.3.1 Resource Surplus

[0021] In the case of resource surplus system state, the business value of a resource 104 is calculated as:

$$\text{BusinessValue}_{\text{Resource}_n} = \sum_{i=1}^{\text{maxskills}} (A_{n,i} \times BR_{1,i}) = RSBV_n$$

2.3.2 Work Item Surplus

[0022] In the case of work item surplus system state, the business value of a work item 100 is calculated as:

$$\text{BusinessValue}_{\text{WorkItem}_n} = \sum_{i=1}^{\text{maxskills}} (A_{1,n} \times BR_{n,i}) = WSBV_n$$

2.4 Calculation of Resource Treatment Value

[0023] Assume that a matrix $T_{\text{availresources}, 3}$, where availresources is the number of resources 104 in the system waiting to service work items 100, represents each resource's activity during the current login session by $T_{n,1}$ = time in seconds since becoming available, $T_{n,2}$ = percent of logged-in time not spent serving work items 100 (the work items' handling time and the work items' associated after-call work), and $T_{n,3}$ = a measure of how much serving of the available work item 100 would move this resource toward its goal (See section on Calculating and Setting Resource Goals.) Other and/or additional treatment metrics may be used, as desired.

[0024] Next, assume that a matrix $TW_{\text{pendingworkitems}, 3}$ represents the weights to be applied to the treatment values T of resources 104 such that $TW_{n,m}$ is the weight for resource n to be applied to $T_{n,m} \forall m$, where $1 \leq m \leq 3$.

[0025] Now, the resource treatment value of a resource 104 is calculated as:

$$\text{ResourceTreatmentValue}_{\text{Resource}_n} = \sum_{i=1}^3 (T_{n,i} \times TW_{n,i}) = RTV_n$$

2.5 Calculating and Setting Resource Goals

[0026] Let $G_{\text{maxskills}, \text{numresources}}$ be a vector containing percent allocation goals up to maxskills for each resource 104 such that

$$\sum_{i=1}^{\text{maxskills}} G_{n,i} = 1, \forall n, \text{ where } n \leq \text{numresources}$$

EP 1 094 655 A1

Now, let $TT_{numresources,maxskills}$ be a vector containing the total time spent by each resource 104 in processing work items 100. This vector is updated as follows:

1. Resource r finishes processing a work item wi .
2. Work item wi has skill weight vector BR_{wi} .
3. Total time of processing T_p is recorded.
4. TT is updated as

$$TT_{r,n} = TT_{r,n} + T_p, \forall n, \text{ where } 0 < n < maxskills \text{ and } BR_{wi,n} > 0$$

[0027] Now, the total time spent handling each skill is available for each resource 104. This total time, along with a prospective new work item 100 and percent allocation goals can be used to calculate whether handling this work item 100 helps or hurts the resource 104 in moving toward the allocation goal as follows:

[0028] Let $PA_{n,maxskills}$ be the actual percent allocation for resource n such that:

$$PA_{n,i} = \frac{TT_{n,i}}{\sum_{j=1}^{maxskills} TT_{n,j}}$$

[0029] Now, the present distance of resource n from its goal is calculated as:

$$DG_n = \sum_{i=1}^{maxskills} |PA_{n,i} - G_{n,i}|$$

[0030] Now, let T_t be the total time that resource 104 has been handling work items 100, and let T_{wi} be the total number of work items 100 handled by resource 104. Then,

$$T_{avg} = \frac{T_t}{T_{wi}}$$

Lastly, let $TTE_{n,maxskill}$ be the estimated total time, and $PAE_{n,i}$ be the estimated percent allocation for resource n if it handles work item wi_{new} with skill vector BR_{new} such that:

$$TTE_{n,i} = TT_{n,i} + T_{avg}, \forall i, \text{ where } 0 < i < maxskills \text{ and } BR_{new,i} > 0$$

$$PAE_{n,i} = \frac{TTE_{n,i}}{\sum_{j=1}^{maxskills} TTE_{n,j}}$$

[0031] Now, the estimated distance of resource n is from its goal is calculated as:

$$DGE_n = \sum_{i=1}^{maxskills} |PAE_{n,i} - G_{n,i}|$$

[0032] Now, improvement vs. goal can be expressed as:

$$\text{Improvement} = \text{DG}_n - \text{DGE}_n$$

- 5 where negative values indicate moving away from the goal and positive values indicate moving toward the goal. However, this would cause some ambiguity in later calculations. So, the improvement measurement is shifted to ensure a positive value as follows:

$$\text{Improvement} = T_{n,3} = \text{DG}_n - \text{DGE}_n + 2 \times \text{maxskills}$$

10 This yields values between zero and $4 \times \text{maxskills}$. This value will be adjusted in later calculations for practical use.

2.6 Calculation of Work Item Treatment Value

- 15 [0033] Assume that a matrix $C_{\text{pendingworkitems},3}$, where pendingworkitems is the number of work items 100 awaiting service in the system, represents each work item's present waiting condition by $C_{n,1}$ = time in seconds that the work item 100 has been waiting for service, $C_{n,2}$ = the estimated time in seconds that the work item 100 will have to wait for service (see section on Calculating Estimated Wait for Service), and $C_{n,3}$ = the time in seconds that the work item 100 is over its target wait time (or zero if not over target wait time). Additional and/or other treatment metrics may be used, 20 as desired.

[0034] Also, assume that a matrix $CW_{\text{pendingworkitems},3}$ represents the weights to be applied to the treatment values C such that $CW_{n,m}$ is the weight for resource n to be applied to $C_{n,m}$ $\forall m$, where $1 \leq m \leq 3$.

[0035] Now we can calculate the work item treatment value of a work item 100 as:

$$\text{WorkItemTreatmentValue}_{\text{WorkItem}_n} = \sum_{i=1}^3 (C_{n,i} \times CW_{n,i}) = WTV_n$$

30 2.7 Calculating Estimated Wait for Service

[0036] Calculation of the estimated wait for service is accomplished with a moving average of past wait times, weighted across the list of skills and skill requirements as follows:

- 35 [0037] First, let $F_{\text{maxskills}}$ be a vector for holding moving averages of past wait times (one moving average for each skill, up to maxskills), let AW be the average number of work items 100 waiting for service, and let TWWI be the total number of waiting work items 100. Now, every time that a work item w_i , having waited time WT, is assigned to a resource 104, F and AW are updated by:

$$40 F_i = F_i \times (100 - BR_{w_i,i}) + WT \times \frac{BR_{w_i,i}}{100}, \forall i, \text{ where } 1 < i < \text{maxskills}$$

$$AW = AW \times 0.9 + TWI \times 0.1$$

- 45 So, not only is this a moving average, it is also a variable moving average with new work items 100 contributing to the moving average between 0 and 10 percent based on their skill needs and weights.

[0038] Now, calculating estimated wait for service EWS based on a present work item w_i and its skill requirements vector BAR is done as follows:

$$50 EWS = C_{n,2} = \frac{TWI}{AW} \sum_{i=1}^{\text{maxskills}} \frac{BR_{w_i,i}}{\sum_{j=1}^{\text{maxskills}} BR_{w_i,j}} \times F_i$$

55

Under normal operating conditions, $\frac{TWI}{AW}$ will be close to 1. However, in the event of a large spike in work volume or a large drop-off in work volume, this will adjust the estimate based on slow-moving averages to more accurately reflect

the state of the system.

3. Making the Decision

- 5 [0039] One final thing remains for resource 104 or work-item 100 selection. The weight of the business value vs. resource treatment value in the case of resource surplus, and the weight of business value vs. work item treatment value in case of work item surplus. Define W_{RSBV} = weight of business value with resource surplus, W_{AT} = resource treatment value with resource surplus, W_{WSBV} = weight of business value with work -item surplus, and W_{CV} = weight of work-item treatment value in the case of work-item surplus. These are administrable values.

10 3.1 Resource Surplus and Resource Selection

- [0040] For the case of resource surplus, we seek to maximize the business value and resource treatment value according to the specified weights by selecting resource 104 that scores the highest as follows:

$$15 \quad \text{Max}[(RSBV_n \times W_{RSBV}) + (RTV_n \times W_{AT})], \text{ where } A_{n,i} > 0 \vee BRR_{1,i} > 0$$

3.2 Work Item Surplus and Work Item Selection

- 20 [0041] For the case of work item surplus, we seek to maximize the business value and work item treatment value according to the specified weights by selecting work item 100 which scores the highest as follows:

$$25 \quad \text{Max}[(WSBV_n \times W_{WSBV}) + (WTV_n \times W_{CV})], \text{ where } A_{1,i} > 0 \vee BRR_{n,i} > 0$$

3.3 Optional: Dynamic Business Value and Work Item Treatment Weights

- 30 [0042] An option to setting predefined weights for business value and work item treatment value in the case of work item surplus is to allow the values to change over time. This change increases the weight of the work item treatment value over time in order to prevent starvation and move closer to the work item's target service time. In this scenario, work items 100 would have initial values of $W_{RSBV} = 1$ and $W_{CV} = 0$. These values would then change over time (during each evaluation) as:

$$35 \quad W_{CV} = \frac{\text{present wait time}}{\text{target wait time}}$$

or 1, whichever is greater, and

$$40 \quad W_{RSBV} = 1 - W_{CV}$$

This would start the calculation with the most weight on the skills of resource 104 and move to applying the most weight to ensuring fair treatment of work item 100.

4. Scaling Results for Practical Application

- 45 [0043] The above algorithm selects a resource 104 or a work item 100 based on a highest score. However, determining the weights of each of the values that result in an optimum solution for the system can be impractical. For instance, if resource 104 scores very high in business value ($10 \times 10 = 100$) but work items 100 have been waiting for an average of 5 minutes, the work item treatment value (WTV) could be as high as 300. So, as work items 100 age, the WTV has an increased effect on the overall selection. This is undesirable.

- 50 [0044] So, to be practically more applicable, the calculation of each of the selection values must be scaled. One will need a scaling value for each of the calculations that are performed either for all resources 104 or all work items 100 as follows (denoting scaling values as S):

$$55 \quad S_{RSBV} = \frac{100}{\text{Max}[RSBV_n]}$$

EP 1 094 655 A1

$$S_{WSBV} = \frac{100}{\text{Max}[RSBV_n]}$$

$$S_{T_i} = \frac{100}{\text{Max}[T_{n,i}]}, 1 \leq i \leq 3$$

$$S_{CI} = \frac{100}{\text{Max}[C_{n,i}]}, 1 \leq i \leq 3$$

$$S_T = \frac{100}{\text{Max}[T_n]}$$

$$S_c = \frac{100}{\text{Max}[C_n]}$$

Now, one can express the scaled values for RSBV, WSBV, RTV, and WTV as follows:

$$\text{ScaledBusinessValue}_{\text{Resource}} = S_{RSBV} RSBV_n = WRSBV_n$$

$$\text{Scaled BusinessValue}_{\text{WorkItem}_n} = S_{WSBV} WSBV_n = WWSBV_n$$

$$\text{PartialScaledResourceTreatmentValue}_{\text{Resource}_n} = \sum_{i=1}^3 (S_{T_i} \times T_{n,i} \times TW_{n,i}) = PWRTV_n$$

$$\text{PartialScaledWorkItemTreatmentValue}_{\text{WorkItem}_n} = \sum_{i=1}^3 (S_{CI} \times C_{n,i} \times CW_{n,i}) = PWWTW_n$$

$$\text{ScaledResourceTreatmentValue}_{\text{Resource}_n} = PWRTV_n S_T = WRTV_n$$

$$\text{ScaledWorkItemTreatmentValue}_{\text{WorkItem}_n} = PWWTW_n S_c = WWTV_n$$

[0045] The net result of the calculation is that each of the scaled values WRSBV, WWSBV, WRTV, and WWTV is between 0 and 100. Now, regardless of the units of measure or scaling internal to each of the value's initial configuration, one can consistently express the weight that these values have on the overall resource 104 and work item 100 selection.

$$\text{Max}[(WSBV_n \times W_{RSBV}) + (WRTV_n \times W_{AT})], \text{ where } A_{n,i} > 0 \text{ and } BRR_{1,i} > 0.$$

$$\text{Max}[(WWSBV_n \times W_{WSBV}) + (WWTV_n \times W_{CV})], \text{ where } A_{1,i} > 0 \text{ and } BRR_{n,i} > 0.$$

[0046] Note that the weighting for the components of resource treatment value ($T_{n,i}$) and work item treatment value ($C_{n,i}$) are scaled by the above calculations as well.

5. An Example

[0047] Look at an example of resource surplus (Resource Selection) work item 100-to-resource 104 matching to

EP 1 094 655 A1

illustrate the concepts defined above. Assume that we have two resources 104, Jane and Jeff. And, we have skills 1-6, English, Chinese, Tech-support, Sales, PC, and UNIX. Jeff speaks English well (skill level 10), speaks Chinese (skill level 5), and has been trained in tech support (skill level 8) and UNIX (skill level 10). Jane speaks English (skill level 10), is trained and experienced in Sales (skill level 10), is just learning tech support (skill level 2), and has experience in PC (skill level 7) and UNIX (skill level 6). Also, assume that both Jeff and Jane have logged in and are waiting to receive work items 100.

[0048] Now, the matrix A of available resources looks like this:

$$A = \begin{bmatrix} 10 & 5 & 8 & 0 & 0 & 10 \\ 10 & 0 & 2 & 10 & 7 & 6 \end{bmatrix}$$

Further assume that Jeff has been idle for 1 minute and has been on calls 75% of the day. Jane has been idle for 3 minutes and on calls 50% of the day. Now, the matrix T looks like this:

$$T = \begin{bmatrix} 60 & 25 & 0 \\ 180 & 50 & 0 \end{bmatrix}$$

Now, a work item 100 -a call-arrives in the system. The work item is qualified with the following requirements: English (weight 10), Tech support (weight 10), and UNIX (weight 5). All three of these skills are *required*. Now, the matrix BR and matrix BRR look like this:

$$BR = [10 \ 0 \ 10 \ 0 \ 0 \ 5]$$

$$BRR = [1 \ 0 \ 1 \ 0 \ 0 \ 1]$$

[0049] Lastly, when the work item 100 arrives, it is assigned the following weights:

$$TW = [.25 \ .75 \ 0]$$

$$W_{RSBV} = .2$$

$$W_{AT} = .8$$

Now, one can calculate the best selection as:

$$RSBV_{Jeff} = 230$$

$$RSBV_{Jane} = 150$$

$$WRSBV_{Jeff} = 230 \frac{100}{230} = 100$$

$$WRSBV_{Jane} = 150 \frac{100}{230} = 65.22$$

$$PWRTV_{Jeff} = \frac{100}{180}(60)(.25) + \frac{100}{50}(25)(.75) + 0 = 45.83$$

$$PWRTV_{Jane} = \frac{100}{180}(180)(.25) + \frac{100}{50}(50)(.75) + 0 = 200$$

$$WRTV_{Jeff} = \frac{100}{200}(45.83) = 22.92$$

5 $WRTV_{Jane} = \frac{100}{200}200 = 100$

Total value for Jeff:

10 $100(.2) + 22.92(.8) = 40.33$

Total value for Jane:

15 $65.22(.2) + 100(.8) = 93.044$

[0050] Therefore, Jane is selected to handle the work item. Note that Jeff scored higher in business value and Jane scored higher in resource fairness value. However, due to the 80% weight on the resource fairness value, the work item was delivered to Jane.

20 **6. Selection Arrangement Realization**

6.1. Resources list

[0051] In order to evaluate a resource 104 and assign it to the best work items 100, it must be presented to the system classified according to its specific capabilities for service. Selection arrangement 106 of FIG. 1 therefore includes a list 116 of all resources 104 in the system of FIG. 1 and of their qualifications. These qualifications include both relatively static as well as dynamic data, and are illustrated in FIG. 2. Qualifications 200 for each resource 104 include a skills vector 202, which is a list of all of the skills possessed by resource 104. Qualifications 200 for each resource 104 further include a skill-level vector 204, which indicates the level of skill of this resource 104 for each skill possessed by this resource 104, and a skill allocation goals vector 208, which indicates present allocation goals for all skills possessed by this resource 104. These are relatively static, administered, values. Qualifications 200 further include measured values, such as a skill times vector 208 which indicates for each skill the total amount or percentage of time spent by this resource 104 in processing work items 100 that needed this skill. (If a work item 100 processed by a resource 104 requires a plurality of skills of that resource 104, each required skill's skill time is credited with the time that resource 104 spent processing the work item 100.) Measured values further include a worktime vector 210 which indicates one or more of the following: the total time that resource 104 has been logged in, the total time that resource 104 has spent in live communication with customers (in-call time), the total time other than in-call time that resource 104 has spent processing calls (ACW time), the total time that resource 104 has been busy, the total time that resource 104 has been ready to process work items 100, and the total time (T_p) that resource 104 has spent processing work items 100. The metrics of worktime vector 210 correspond to like metrics that are conventionally maintained for agents in ACD systems, and are computed in the same manner. Qualifications 200 further include state information 212 that indicates the present state of the corresponding resource 104 and the time of the last state change of resource 104. The latter value is used to determine the amount of time that resource 104 has been idle since last processing a work item 100. Idle resources 104 form an idle resource list 120 which is a subset of resource list 116.

45 6.1.1 Unitary Skills

[0052] Unitary skills are individual, independent skills. Skills such as English, Spanish, Sales, Tech Support, UNIX, Windows, and Macintosh fall into this category. These are also the most simple to administer. Each skill is assigned a number starting at 1 such that $A_{n,m}$ represents the skill level of resource n for the skill m .

6.1.2 Aggregate Skills

[0053] Aggregate skills are slightly more difficult to work with. They are skills that are made up of combinations of unitary skills, described above. Aggregate skills are needed in that there may be a resource 104 capable of handling several skills individually and only in certain combinations. For instance, suppose that there is an agent in a call center who speaks Spanish and knows UNIX, Windows, and Macintosh. Also, suppose that this agent has had some technical support training and therefore is skilled in tech support as well. However, this agent is being eased into the tech support

role. For the first two weeks the agent should only handle Spanish tech support calls for Windows. During the following two weeks, the agent can also take Spanish tech support calls for Macintosh. Finally, the agent is also allowed to handle Spanish tech support calls for UNIX. This scenario is most easily administered with three *aggregate skills*: Spanish Windows Tech Support, Spanish Macintosh Tech Support, and Spanish UNIX Tech Support.

5 [0054] Now, more generally, aggregate skills are administered as follows. Suppose that some aggregate skill g is an aggregate of unitary skills a , b , and c . Now, $A_{n,g}$ represents the skill level of resource n for aggregate skill g , where $g > maxunitskills$, and $maxunitskills$ is the total number of unitary skills.

[0055] This allows for further differentiation of resources 104 by ability to handle not only individual skill requirements but skill requirement combinations as well.

10 6.2 Resource state update

[0056] Dynamic items 206-212 of qualifications 200 of all resources 104 in resource list 116 are dynamically updated and kept current by a resource state update 118 in FIG. 1. Resource state update 118 provides an interface to which applications can send information to update the state of resources 104 as necessary. Resource state update 118 receives the notifications of resource 104 state-change events and updates list 116 and 120 contents accordingly.

15 6.3 Work Item Classifier

20 [0057] In order to evaluate a work item 100 and distribute it to the best resource 104, it must be presented to the system fully classified according to its specific needs for service. This classification is performed by work item classifier 110 in FIG. 1. Classifications 300 that classifier 110 needs to provide for each work item 100 are outlined below and are illustrated in FIG.3.

25 6.3.1. Qualifying for Calculation of Business Value

[0058] Each work item's classification 300 includes a skills vector 302, which is a list of all possible skills 1-M that a work item 100 can have. Each skill that is required or simply desired for the handling of a work item 100 must be added to the work item classification 300 for each of the categories below.

30 6.3.1.1 Unitary Skills

[0059] Each qualification 300 includes a BR vector 306, which is a list of the skill weights assigned for this work item 100 to each of the skills in skills vector 302. For each unitary skill associated with work item n , a weight (illustratively an integer between 0 and 10) is assigned such that $BR_{n,m} = w$ where $1 \leq m \leq maxunitskills$, $0 \leq w \leq 10$, and $maxunitskills$ is the number of unitary skills.

35 6.3.1.2 Aggregate Skills

40 [0060] BR vector 306 includes both unitary skills and aggregate skills. For each aggregate skill associated with work item n , a weight (integer between 0 and 10) is assigned such that $BR_{n,m} = w$ where $maxskills < m \leq maxskills$, $0 \leq w \leq 10$, and $maxskills$ is the total number of unitary and aggregate skills combined.

45 6.3.1.3 Skill Requirements

[0061] Each classification 300 includes a BRR vector 304 indicating which of the skills in skill vector 302 are required by this work item 100. For each skill, both aggregate and unitary, associated with work item n , a value of true or false must be assigned to BRR such that $BRR_{n,m}$ indicates whether or not a skill m is *required* for work time n . Vectors 302, 304 and 306 together represent a business value of work item 100. Note that it is possible for a skill to contribute to the business value calculation but not be a *required* skill. For example, suppose that some agents in a call center had been trained in effective communication, but this is not *required* to handle a call. Those agents could score higher in business value, having had that training. However, agents who were not trained would not be excluded from the selection process if the skill had a $weight > 0$ in BRR but not a value of true in the requirements vector BRR .

55 6.3.2 Qualifying Weights for Resource Fairness Values

[0062] Each classification 300 includes a qualifying weights for resource fairness values (QWRFV) vector 308. The values, for resource n , of $TW_{n,m}$ must be filled in for fairness values one through three ($1 \leq m \leq 3$). $TW_{n,1}$ is the weight

to be given to the time since resource n has become available (or is it the idle time?), $TW_{n,2}$ is the weight to be given to the percentage of time that resource n has not spent handling work items 100, TW_n , is the weight to be given to how much the processing of the current work item 100 would move resource 104 toward its service objective. Although the values of TW can be anything, it is most appropriate to imagine that

5

$$\sum_{i=1}^{i=3} TW_{n,i} = 1$$

- 10 for a *percentage weight* of each of the values for some resource n . In the simple default case, it is expected that a work item 100 will have only one set of TW values in common for all resources 104.

6.3.3 Qualifying Weights for Work Item Fairness Values

- 15 [0063] Each classification 300 includes a qualifying weights for work item fairness values (QWWIFV) vector 312. As with resources above, the values, for work item n , of $CW_{n,m}$ must be filled in for fairness values one through three ($1 \leq m \leq 3$). $CW_{n,1}$ is the weight to be given to time that work item 100 has spent waiting for processing, $CW_{n,2}$ is the weight to be given to the work item's estimated total wait time, and $CW_{n,3}$ is the weight to be given to the waiting time by which work item 100 has exceeded its target service time. Although the values of CW can be anything, it is most appropriate to imagine that

20

$$\sum_{i=1}^{i=3} CW_{n,i} = 1$$

25

- for a *percentage weight* of each of the values for some resource n .

6.3.4 Qualifying Weights for Business Value

- 30 [0064] When classifier 110 passes a new work item 100 to the system for distribution, it is assumed that classifier 110 knows nothing of the state of the system and therefore must provide enough information to make a decision in any state.

35

- [0065] To be able to make a decision in a resource surplus state, each classification 300 provides resource surplus weights 314 that include the weight of business value with resource surplus W_{RSBV} , and the weight of resource fairness with resource surplus W_{AT} .

- 40 6.3.4.2 Work Item Surplus

[0066] To be able to make a decision in a work item surplus state, each classification 300 provides work-item surplus weights 316 that include the weight of business value with work-item surplus W_{WSBV} , and the weight of work-item fairness with work-item surplus W_{CV} .

45

6.3.5 Qualifying Target Wait Time

- [0067] Lastly, each classification 300 provides the target wait time for work item 100, *Target* 318.

- 50 6.3.6 Classification Generation

- [0068] Illustratively, values 308-318 are pre-administered for different business values (values of fields 302-306), so that classifier 110 need only determine the business values (values of fields 302-306)--illustratively in the same manner as is done in conventional skills-based ACD systems--and then populates fields 308-318 with the corresponding administered values.

6.4. Selection Engine

[0069] FIGS. 4 and 5 show an illustrative implementation of selection engine 114. FIG. 4 shows the operation of engine 114 when a classified work item 100 becomes available, while FIG. 5 shows its operation when a resource 104 becomes available.

6.4.1. Resource Surplus

[0070] When a classified work item 100 is or becomes available in waiting work-items list 112, at step 400, engine 114 checks idle resources list 120 to determine if any resource 104 is available to handle the work item, at step 402. If idle resources list 120 is empty, engine 114 returns work-item 100 to list 112, at step 410, and ends its operation, at step 412, until such time as a resource 104 becomes available. If idle resources list 120 is not empty, engine 114 compares skills requirements 304 of the work item's classification 300 with the skill levels 204 of the available resources' qualifications 200 to determine if an available resource 104 has the skills that are required by available work item 100, at step 414. If not, engine 114 proceeds to steps 410 et seq., if so, engine 114 proceeds to step 420 et seq.

[0071] At step 420, engine 114 computes the business value (RSBV) for each available resource 104 that has the skills required by available work item 100. The computation is effected as described in Section 2.3.1 above. Engine 114 then computes the resource treatment value (RTV) for each available resource 104 that has the required skills at step 422. The computation is effected as described in Sections 2.4 and 2.5 above. Engine 114 then selects an available resource 104 based on the combined weighted RSBV and RTV score, at step 424. This computation and selection is effected as described in Section 3.1 above. Engine 114 then removes the selected resource from idle resources list 120, at step 426, requests match-maker 102 to assign available work item 100 to selected resource 104, at step 428, and ends its operation, at step 430, until another classified work item 100 or resource 104 becomes available.

6.4.2 Work-Item Surplus

[0072] When a resource 104 is or becomes available on idle resources list 120, at step 500, engine 114 checks waiting work items list 112 to determine if any work item 100 is available for handling, at step 502. If waiting work items list 112 is empty, engine 114 returns resource 104 to list 120, at step 510, and ends its operations until such time as a work item 100 becomes available, at step 512. If waiting work items list 112 is not empty, engine 114 compares skill levels 204 of the resource's qualifications 200 with the skills requirements 304 of the available work items' classifications 300 to determine if the resource's skills match the skill requirements of an available work item 100, at step 514. If not, engine 114 proceeds to steps 510 et seq.; if so, engine 114 proceeds to steps 520 et seq.

[0073] At step 520, engine 114 computes the business value (WSBV) for each available work item 100 whose skill needs match the skills of resource 104. The computation is effected as described in Section 2.3.1 above. Engine 114 then computes the work-item treatment value (WTW) for each available work item 100 whose skill needs match the skills of resource 104, at step 522. The computation is effected as described in Sections 2.6 and 2.7 above. Engine 114 then selects an available work item 100 based on the combined weighted WSDV and WTW score, at step 524. This computation and selection is effected as described in Section 3.2 above. Engine 114 then removes the selected work-item 100 from waiting work items list 112, at step 526, requests match-maker 102 to assign available resource 104 to selected work item 100, at step 528, and ends its operation, at step 530, until another resource 104 or classified work item 100 becomes available.

6.5 Variants

[0074] Of course, various changes and modifications to the illustrative embodiment described above will be apparent to those skilled in the art. For example, the compact nature of the algorithms allows for distribution of the system across multiple sites. It would be quite effective for multiple sites to update present values of their forecast vector F, their average number of waiting work items AW, the number of current waiting work items TWI, and a vector indicating serviceable skills (to avoid sending a work item to a site that cannot service it) at a central location. This central location would then have enough information to distribute work items across the multiple sites based on estimated time to service. Or, this information could be delivered to the appropriate site initially by an external process accessing this central location (i.e., a pre-route solution). Such changes and modifications can be made without departing from the spirit and the scope of the invention and without diminishing its attendant advantages. It is therefore intended that such changes and modifications be covered by the following claims except insofar as limited by the prior art.

Claims

1. A method of selecting a resource for a work item, comprising;

5 determining available resources that possess skills needed by the work item;
 for each of the determined resources, determining a business value of having the resource service the work
 item;
 for each of the determined resources, determining a value to the resource of servicing the work item; and
 10 selecting a determined resource that has a best combined value of the business value and the value to the
 resource, to serve the work item.

2. The method of claim 1 wherein:

15 determining a business value comprises
 determining the business value weighted by a business value weight corresponding to the work item;
 determining a value to the resource comprises
 determining the value to the resource weighted by a resource value weight corresponding to the work item; and
 selecting comprises
 20 selecting a determined resource that has a best combined value of the weighted business value and the
 weighted value to the resource.

3. The method of claim 2 wherein:

25 determining a business value comprises
 determining a weighted business value as a product of (a) the business value weight corresponding to the work
 item and (b) a sum of products of a level of each said needed skill of the resource and a weight of said needed
 skill of the work item; and
 determining a value to the resource comprises
 determining a weighted resource treatment value as a product of (c) a resource treatment weight correspond-
 30 ing to the work item and (d) a sum of products of each treatment of the resource and a weight of said treatment
 of the resource.

4. The method of claim 3 wherein:

35 the sums of products are scaled sums, and
 the treatments are scaled treatments.

5. The method of claim 4 wherein:

40 selecting comprises
 selecting the determined resource that has a highest sum of the weighted business value and the weighted
 resource treatment value.

6. The method of claim 3 wherein:

45 the resource treatments of a resource comprise a time since the resource became available and a time that
 the resource has not spent serving work items.

7. The method of claim 6 wherein:

50 the treatments of the resource further comprise a measure of an effect that serving of the work item would have
 on a goal of the resource.

8. The method of claim 7 wherein:

55 the measure of the effect comprises a difference between (a) a distance of an actual allocation of worktime of
 the resource among skills from a goal allocation of the worktime of the resource among the skills and (b) a dis-
 tance of an estimated allocation of the worktime of the resource among the skills if the resource serves the

work item from the goal allocation.

9. A method of selecting a resource for a work item, comprising:

5 determining available resources that possess skills needed by the work item;
 for each of the determined resources, determining a business value comprising a sum across all skills of a
 product of a skill level of the resource in the skill and a skill weight of the work item for the skill;
 for each of the determined resources, determining a resource treatment value comprising a sum across all
 resource treatments of a product of a value of the resource for the resource treatment and a weight of the work
 item for the resource treatment; and
 10 selecting a determined resource that has a best combined score of its business value and its resource treat-
 ment value, to serve the work item

10. The method of claim 9 wherein:

15 the resource treatments of a resource comprise a time since the resource became available, a time that the
 resource has spent not serving work items, and a measure of an effect that serving the work item would have
 on a goal of the resource.

20 11. The method of claim 9 wherein:

determining a business value comprises
 determining a scaled business value comprising the business value scaled by a first scaling factor that is com-
 mon to all of the determined resources;
 25 determining a resource treatment value comprises
 for each resource treatment, determining a scaled value of the resource comprising the value of the resource
 for that resource treatment scaled by a scaling factor that is common for that resource treatment to all of the
 determined resources, and
 determining a scaled resource treatment value comprising a sum, scaled by a second scaling factor that is
 30 common to all of the determined resources, across all resource treatments of a product of the scaled value of
 the resource for the resource treatment and a weight of the work item for the resource treatment; and
 selecting comprises
 selecting a determined resource that has a best sum of its scaled business value and its scaled resource treat-
 ment value to serve the work item.

35 12. The method of claim 11 wherein:

each scaling factor comprises a fraction having in its denominator a maximum value of the value to which said
 scaling factor applies of any of the resources.

40 13. A method of selecting a work item for a resource, comprising:

determining available work items that need skills possessed by the resource;
 for each of the determined work items, determining a business value of having the resource service the work
 item;
 45 for each of the determined work items, determining a value to the work item of being serviced by the resource;
 and
 selecting a determined work item that has a best combined value of the business value and the value to the
 work item to be served by the resource.

50 14. The method of claim 13 wherein:

determining business value comprises
 determining the business value weighted by a business value weight corresponding to the work item;
 55 determining a value to the work item comprises
 determining the value to the work item weighted by a work item value weight corresponding to the work item;
 and
 selecting comprises

selecting a determined work item that has a best combined value of the weighted business value and the weighted value to the work item.

15. The method of claim 14 wherein:

- 5 determining a business value comprises
determining a weighted business value as a product of (a) the business value weight corresponding to the work item and (b) a sum of products of a level of each said needed skill of the resource and a weight of said needed skill of the work item; and
- 10 determining a value to the work item comprises
determining a weighted work item treatment value as a product of (c) a work item treatment weight corresponding to the work item and (d) a sum of products of each treatment of the work item and a weight of said treatment of the work item.

15 16. The method of claim 15 wherein:

- the sums of products are scaled sums, and
the treatments are scaled treatments.

20 17. The method of claim 16 wherein:

- selecting comprises
selecting the determined work item that has a highest sum of the weighted business value and the weighted work item treatment value.

25 18. The method of claim 15 wherein:

- the work item treatments of a work item comprise a time that the work item has been waiting for service and an estimated time that the work item will have to wait for service.

30 19. The method of claim 18 wherein:

- the treatments of a work item further comprise a time by which the work item has exceeded its target wait time.

35 20. The method of claim 18 wherein:

- the estimated wait time that the work item will have to wait for service comprises a product of (a) a ratio of a total number of work items waiting for service and an average number of work items waiting for service and (b) a sum of average wait times of individual said needed skills each weighted by a ratio of the weight of said individual skill and a sum of the weights of the needed skills.

21. A method of selecting a work item for a resource, comprising:

- determining available work items that need skills possessed by the resource;
- 45 for each of the determined work items, determining a business value comprising a sum across all skills of a product of a skill level of the resource in the skill and a skill weight of the work item for the skill;
- for each of the determined work items, determining a work item treatment value comprising a sum across all work item treatments of a product of the value of the work item for the work item treatment and a weight of the work item for the work item treatment; and
- 50 selecting a determined work item that has a best combined score of its business value and work item treatment value, to be served by the resource.

22. The method of claim 21 wherein:

- 55 the work item treatments of a work item comprise a time that the work item has spent waiting to be serviced, an estimated time that the item will spend waiting to be serviced, and a time by which the work item has exceeded its target waiting time.

23. The method of claim 21 wherein:

determining a business value comprises
determining a scaled business value comprising the business value scaled by a first scaling factor that is common to all of the determined work items;
determining a work item treatment value comprises
for each work item treatment, determining a scaled value of the work item comprising the value of the work item for that work item treatment scaled by a scaling factor that is common for that work item treatment to all of the determined work items, and
determining a scaled work item treatment value comprising a sum, scaled by a second scaling factor that is common to all of the determined work items, across all work item treatments of a product of the scaled value of the work item for the work item treatment and a weight of the work item for the work item treatment; and
selecting comprises
selecting a determined work item that has a best sum of its scaled business value and its scaled work item treatment value, to be served by the resource.

24. The method of claim 23 wherein:

each scaling factor comprises a fraction having in its denominator a maximum value of the value to which said scaling factor applies of any of the work items.

25. An apparatus that performs the method of any one of the claims 1-24.

26. A computer-readable medium containing instructions which, when executed in a computer, cause the computer to perform the method of any one of claims 1-24.

**ANNEX TO THE EUROPEAN SEARCH REPORT
ON EUROPEAN PATENT APPLICATION NO.**

EP 00 30 9154

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
